Scientific summary

Background

Chronic ulceration of the foot represents a major problem in people with diabetes mellitus, and ulcers of the heel present particular difficulties, with only around 40% healing within 6 months. However, a recent study suggested that the use of lightweight fibreglass heel casts was associated with a marked improvement in healing time. The aim of the present study was to use a definitive, multicentre, randomised controlled trial to compare the effectiveness of such casts in addition to usual care with usual care alone in the management of heel ulcers of National Pressure Ulcer Advisory Panel/European Pressure Ulcer Advisory Panel (NPUAP/EPUAP) grades 2–4 in people with type 1 or type 2 diabetes mellitus, and to explore the cost-effectiveness of such casts.

Methods

The participants were randomised to receive either usual clinical care in a specialist centre or a fibreglass heel cast in addition to usual care in a parallel, group design clinical trial. Randomisation was stratified by NPUAP/EPUAP grade (depth) and ulcer cross-sectional area (<100 mm² or ≥100 mm²) using blocks of variable size. The primary outcome was healing (confirmed by a blinded observer and maintained for at least 4 weeks) at or before 24 weeks. The target sample size was 496, and based on a difference in primary outcome of 55% (intervention) and 40% (control), allowing for 30% attrition. Secondary outcomes included the time taken for the ulcer to heal, secondary infection, new ulceration, hospital admission, minor and major amputation and health status. The primary analysis estimated the absolute and relative effectiveness on ulcer healing at or before 24 weeks, comparing the intervention group with usual care. A within-trial health economic analysis was undertaken to estimate the incremental cost per quality-adjusted life-year (QALY) and incremental cost per percentage of healed ulcers at 24 weeks.

Results

A total of 509 participants with ulceration of the heel complicating diabetes mellitus [68% male, 15% type 1 and 85% type 2 diabetes, mean age 67.5 years (standard deviation 12.4 years)] and attending one of 35 specialist centres in the UK were randomised 1:1 to either the intervention arm (n = 256) or the control arm (n = 253) of the study. Primary outcome data were available for 212 participants in the intervention arm and for 213 participants in the control arm. The median (25th–75th centile) ulcer area at baseline was 275 mm² (104–683 mm²) in the intervention group and 206 mm² (77–649 mm²) in the control group, and the ulcer grades in the two groups were identical (grade 2, 32%; grade 3, 62%; and grade 4, 6%). When analysed by intention to treat, 44% (n = 94) of the intervention group’s ulcers had healed at or before 24 weeks, compared with 37% (n = 80) of the control group’s [odds ratio 1.42, 95% confidence interval (CI) 0.95 to 2.14; p = 0.088; risk difference 8%, 95% CI −1% to 17%; p = 0.087]. There were no differences between the two groups for any of the secondary outcome measures, including the reduction of local pain at 2 and 4 weeks. There was no clear excess of adverse events in either group.

The results of the cost-utility analysis showed that usual care dominated the intervention, that is, usual care had lower costs and more QALY gains under the base case (the incremental cost-effectiveness ratio was −£35,478.95), and a one-way sensitivity analysis indicated that the intervention would be cost-effective (£9057.89 per QALY gain) only when the lower-bound 95% CI cost estimate was used. The probability of the intervention being cost-effective at a societal willingness-to-pay threshold of £20,000 was estimated at 5%.
The adjusted analysis estimated that the incremental cost of a 1% likelihood of achieving a healed ulcer was £9.63 (£963 per additional healed heel ulcer).

**Discussion**

The data suggest that there may be a small increase in healing with the use of a heel cast, but the estimate was not sufficiently precise to provide strong evidence of an effect. There was no evidence of any subgroup in which the intervention appeared to be particularly effective. There was also no evidence of any benefit in terms of reduced local pain. The results of the health economic analysis suggest that it is unlikely that the intervention represents good value for money. The provision of a lightweight heel cast may be of benefit to some individuals, but we found no evidence to justify the routine adoption of the use of this treatment in clinical practice. It is unlikely that further study of this intervention will have an impact on usual clinical care, and so future efforts should be directed towards other interventions designed to improve the healing of ulcers in this population.

**Trial registration**

This trial is registered as ISRCTN62524796.

**Funding**

Funding for this study was provided by the Health Technology Assessment programme of the National Institute for Health Research.
Health Technology Assessment

Criteria for inclusion in the Health Technology Assessment journal

Reports are published in Health Technology Assessment (HTA) if (1) they have resulted from work for the HTA programme, and (2) they are of a sufficiently high scientific quality as assessed by the reviewers and editors.

Reviews in Health Technology Assessment are termed ‘systematic’ when the account of the search appraisal and synthesis methods (to minimise biases and random errors) would, in theory, permit the replication of the review by others.

HTA programme

The HTA programme, part of the National Institute for Health Research (NIHR), was set up in 1993. It produces high-quality research information on the effectiveness, costs and broader impact of health technologies for those who use, manage and provide care in the NHS. ‘Health technologies’ are broadly defined as all interventions used to promote health, prevent and treat disease, and improve rehabilitation and long-term care.

The journal is indexed in NHS Evidence via its abstracts included in MEDLINE and its Technology Assessment Reports inform National Institute for Health and Care Excellence (NICE) guidance. HTA research is also an important source of evidence for National Screening Committee (NSC) policy decisions.

For more information about the HTA programme please visit the website: http://www.nets.nihr.ac.uk/programmes/hta

This report

The research reported in this issue of the journal was funded by the HTA programme as project number 09/01/53. The contractual start date was in February 2012. The draft report began editorial review in March 2016 and was accepted for publication in December 2016. The authors have been wholly responsible for all data collection, analysis and interpretation, and for writing up their work. The HTA editors and publisher have tried to ensure the accuracy of the authors’ report and would like to thank the reviewers for their constructive comments on the draft document. However, they do not accept liability for damages or losses arising from material published in this report.

This report presents independent research funded by the National Institute for Health Research (NIHR). The views and opinions expressed by authors in this publication are those of the authors and do not necessarily reflect those of the NHS, the NIHR, NETSCC, the HTA programme or the Department of Health. If there are verbatim quotations included in this publication the views and opinions expressed by the interviewees are those of the interviewees and do not necessarily reflect those of the authors, those of the NHS, the NIHR, NETSCC, the HTA programme or the Department of Health.
