Scientific summary

Background

Obesity and excess weight gain in pregnancy are associated with adverse maternal and fetal outcomes. Maternal age, parity, ethnicity and underlying medical conditions influence the risk of complications. Diet and physical activities have the potential to reduce weight gain and alter pregnancy outcomes. Variation in the effect of these interventions across subgroups of women may have implications for clinical management and provision of care. The association of gestational weight gain (GWG) with complications in pregnancy needs evaluation using robust data.

Objectives

Primary

1. To assess if the effects of diet- and physical activity-based interventions on (1) GWG, (2) composite maternal outcomes and (3) composite fetal/neonatal outcomes vary in subgroups of women based on body mass index (BMI) at booking, age, parity, ethnicity and underlying medical conditions.

Secondary

1. To evaluate the association of GWG and adverse pregnancy outcomes in women and their infants.
2. To assess adherence to the Institute of Medicine (IOM)-recommended weight-gain targets in normal weight, overweight and obese pregnant women and rates of maternal and fetal complications.
3. To identify the predictors of GWG in pregnancy based on maternal characteristics such as parity, pre-pregnancy or early pregnancy BMI, ethnicity, smoking, diet, physical activity and socioeconomic status.
4. To evaluate the cost-effectiveness of interventions.
5. To undertake network meta-analysis to determine the rank order of interventions based on effectiveness.

Methods

We undertook individual participant data (IPD) meta-analysis by using a prospective protocol in line with existing recommendations, and complied with the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) guidelines for IPD meta-analysis in reporting our work. We searched MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, Database of Abstracts of Reviews of Effects and Health Technology Assessment database, from October 2013 to March 2015, for relevant studies (to update a previous search). Randomised trials that assessed the effects of diet, physical activity or mixed-approach interventions on GWG, composite maternal and fetal/neonatal outcomes were included. The composite maternal outcome included gestational diabetes mellitus (GDM), pre-eclampsia (PE) or pregnancy-induced hypertension (PIH), preterm delivery and Caesarean section. The composite fetal outcomes included intrauterine death, small for gestational age, large for gestational age and admission to the neonatal intensive care unit (NICU). Researchers from the International Weight Management in Pregnancy Collaborative Network shared the primary data.

We obtained summary estimates of effects and 95% confidence intervals (CIs) for each intervention type and outcome, with a two-step IPD random-effects meta-analysis, for all women combined and for each...
subgroup of interest. We synthesised the differences in effects between subgroups in a two-step IPD random-effects meta-analysis. In the first stage, we either fitted a linear regression adjusted for baseline (for continuous outcomes) or a logistic regression model (for binary outcomes) in each study separately; in the second stage, the pertinent effect estimates were then combined across studies using a random-effects meta-analysis model estimating via restricted maximum likelihood. We quantified the relationship between weight gain and pregnancy complications. A model-based economic evaluation was undertaken to assess the cost-effectiveness of the interventions.

Results

Of the 74 eligible studies (17,727 women), 36 (12,434 women) contributed data to the IPD meta-analysis: 33 (9320 women) evaluated GWG, 24 (8852 women) reported all four components of the composite maternal outcomes and 18 (7981 women) assessed all four components of the fetal/neonatal composite outcomes.

Effect of diet- and physical activity-based interventions on maternal and fetal outcomes

Diet- and physical activity-based interventions reduced GWG by an average of $-0.70$ kg [95% CI $-0.92$ to $-0.48$ kg, 95% prediction interval (PI) $-1.24$ to $-0.16$ kg; 33 studies, 9320 women] compared with the control group in the IPD meta-analysis. The odds of composite adverse maternal outcome were not significantly reduced by the interventions [summary odds ratio (OR) 0.90, 95% CI 0.79 to 1.03, 95% PI 0.68 to 1.20]. The interventions had no effect on fetal/neonatal outcomes (summary OR 0.94, 95% CI 0.83 to 1.08, 95% PI 0.74 to 1.21).

The IPD meta-analysis showed a significant reduction in rates of Caesarean section (OR 0.91, 95% CI 0.83 to 0.99; 32 studies contributing data, 11,410 women). The decreases in rates of other individual maternal outcomes [such as GDM (OR 0.89, 95% CI 0.72 to 1.10; 27 studies contributing data, 9427 women), PE or PIH (OR 0.95, 95% CI 0.78 to 1.16; 22 studies, 9618 women) and preterm birth (OR 0.94, 95% CI 0.78 to 1.13; 32 studies contributing data, 116,876 women)] were not significant.

Sensitivity analysis showed that the beneficial effect on weight gain persisted after adding non-IPD data (summary mean difference $-1.13$ kg, 95% CI $-1.58$ to $-0.68$ kg; 60 studies, 12,895 women). Meta-analysis of published aggregate data showed a significant reduction only in GDM (OR 0.78, 95% CI 0.64 to 0.95; 29 studies, 11,118 women) and Caesarean section (OR 0.90, 95% CI 0.82 to 0.99; 37 studies, 11,340 women) compared with the control group. There were no significant reductions in preterm birth (OR 0.80, 95% CI 0.63 to 1.01; 23 studies, 7480 women) and PE or PIH (OR 0.89, 95% CI 0.75 to 1.05; 20 studies, 9198 women). Both aggregate and IPD meta-analyses did not have an effect on fetal/neonatal outcomes.

Differential effect of interventions on gestational weight gain and pregnancy outcomes

The effect of interventions on GWG did not significantly vary with maternal BMI ($-0.02$ kg change in intervention effect per 1 kg/m² increase in BMI, 95% CI $-0.08$ to 0.04 kg), age ($-0.03$ kg change in intervention effect per 1-year increase in age, 95% CI $-0.08$ to 0.02 kg), parity (0.10 kg change in intervention effect for multiparity vs. nulliparity, 95% CI $-0.39$ to 0.60 kg), ethnicity (0.05 kg change in intervention effect for non-Caucasian vs. Caucasian, 95% CI $-1.27$ to 1.37 kg) or underlying medical conditions (1.51 kg change in intervention effect for women with at least one condition vs. none, 95% CI $-2.01$ to 5.02 kg).

We did not identify any significant change in treatment effect for composite maternal outcomes in subgroups based on maternal BMI (no change in effect for every 1 kg/m² increase in BMI, OR 1.00, 95% CI 0.98 to 1.02), age (1% increase in effect for every 1-year increase in age, OR 1.01, 95% CI 0.99 to 1.03), parity (3% increase in effect for multiparity vs. nulliparity, OR 1.03, 95% CI 0.75 to 1.39), ethnicity (7% decrease in effect for non-Caucasian vs. Caucasian, OR 0.93, 95% CI 0.63 to 1.37) or underlying

SCIENTIFIC SUMMARY: EFFECTS OF ANTENATAL DIET AND PHYSICAL ACTIVITY ON MATERNAL AND FETAL OUTCOMES

NIHR Journals Library www.journalslibrary.nihr.ac.uk

vi
medical conditions (44% increase in effect for women with at least one condition vs. none, OR 1.44, 95% CI 0.15 to 13.74). For composite fetal/neonatal outcome we observed a 2% lowered effect (OR 0.98, 95% CI 0.95 to 1.00) for every 1 kg/m² increase in booking BMI, which was of borderline significance. There was no significant treatment–covariate interaction for other factors and composite fetal/neonatal outcome. There was significant evidence of small-study effects for GWG (Egger’s test, \( p = 0.038 \)) and the composite maternal outcome (Peter’s test, \( p = 0.036 \)), but not for fetal/neonatal composite outcome (\( p = 0.398 \)).

**Gestational weight gain and pregnancy outcomes**

We did not identify an association between GWG, booking BMI and risk of maternal (summary OR 1.03, 95% CI 0.93 to 1.15) or fetal/neonatal complications (summary OR 1.02, 95% CI 0.91 to 1.15). Adherence to IOM criteria for GWG did not significantly reduce GWG. Increase in maternal age (–0.1 kg, 95% CI –0.14 to –0.06 kg) and multiparity (–0.73 kg, 95% CI –1.24 to –0.23 kg) were significantly associated with GWG.

We refrained from undertaking network meta-analysis, as there were no differences in estimates of effect for GWG between diet-based, physical activity-based and mixed-approach interventions.

**Cost-effectiveness of the intervention**

Diet- and physical activity-based interventions in pregnancy are not cost-effective compared with usual care. Although the primary base-case analysis indicated a small reduction in pregnancy-related complications, the probabilistic sensitivity analysis showed no evidence of significant difference between the intervention and the control arms for either cost or clinical effectiveness. Similarly, the results of the secondary analysis for obese, overweight and normal weight women found no evidence that diet- and physical activity-based interventions are more cost-effective than usual care for any of the subgroups.

**Conclusions**

Interventions based on diet and physical activity in pregnancy reduce GWG, and the effect does not vary by maternal BMI, age, parity, ethnicity or underlying medical conditions. The interventions do not confer any additional benefit for composite maternal and fetal outcomes and are not cost-effective. There is no evidence to support routine use of IOM targets for GWG.

**Recommendations for further research**

The impact of lifestyle interventions in pregnancy on long-term outcomes (such as postpartum weight retention, future risk of diabetes and hypertension, subsequent pregnancy outcomes and childhood obesity) needs evaluation. Randomised trials are required to evaluate the effect of interventions to optimise the pre-pregnancy health of the mother.

**Study registration**

This study is registered as PROSPERO CRD42013003804.

**Funding**

Funding for this study was provided by the Health Technology Assessment programme of the National Institute for Health Research.
Health Technology Assessment

Criteria for inclusion in the Health Technology Assessment journal
Reports are published in Health Technology Assessment (HTA) if (1) they have resulted from work for the HTA programme, and (2) they are of a sufficiently high scientific quality as assessed by the reviewers and editors.

Reviews in Health Technology Assessment are termed ‘systematic’ when the account of the search appraisal and synthesis methods (to minimise biases and random errors) would, in theory, permit the replication of the review by others.

HTA programme
The HTA programme, part of the National Institute for Health Research (NIHR), was set up in 1993. It produces high-quality research information on the effectiveness, costs and broader impact of health technologies for those who use, manage and provide care in the NHS. ‘Health technologies’ are broadly defined as all interventions used to promote health, prevent and treat disease, and improve rehabilitation and long-term care.

The journal is indexed in NHS Evidence via its abstracts included in MEDLINE and its Technology Assessment Reports inform National Institute for Health and Care Excellence (NICE) guidance. HTA research is also an important source of evidence for National Screening Committee (NSC) policy decisions.

For more information about the HTA programme please visit the website: http://www.nets.nihr.ac.uk/programmes/hta

This report
The research reported in this issue of the journal was funded by the HTA programme as project number 12/01/50. The contractual start date was in February 2013. The draft report began editorial review in November 2015 and was accepted for publication in August 2016. The authors have been wholly responsible for all data collection, analysis and interpretation, and for writing up their work. The HTA editors and publisher have tried to ensure the accuracy of the authors’ report and would like to thank the reviewers for their constructive comments on the draft document. However, they do not accept liability for damages or losses arising from material published in this report.

This report presents independent research funded by the National Institute for Health Research (NIHR). The views and opinions expressed by authors in this publication are those of the authors and do not necessarily reflect those of the NHS, the NIHR, NETSCC, the HTA programme or the Department of Health. If there are verbatim quotations included in this publication the views and opinions expressed by the interviewees are those of the interviewees and do not necessarily reflect those of the authors, those of the NHS, the NIHR, NETSCC, the HTA programme or the Department of Health.
