**Declared competing interests of authors:** Robert Howard reports membership of the Health Technology Assessment (HTA) Commissioning Board between 2013 and 2018. John O'Brien reports personal fees from TauRx Pharmaceuticals Ltd (Singapore) and GE Healthcare (Chicago, IL, USA), Eli Lilly and Company (Indianapolis, IN, USA) and Eisai Co., Ltd (Tokyo, Japan), outside the submitted work. Gill Livingston reports membership of the HTA Clinical Trials Board Associate from 2007 to 2010. Peter Bentham reports personal fees from TauRx Pharmaceuticals Ltd outside the submitted work. Craig Ritchie reports other payments from Roche Holding AG (Basel, Switzerland), Nutricia International B.V. (Zoetermeer, the Netherlands), Actinogen Medical (Sydney, NSW, Australia), Kyowa Hakko Kirin Co., Ltd (Singapore), Biogen Inc. (Cambridge, MA, USA) and Merck Sharp & Dohme Corp. (Kenilworth, NJ, USA) and grants from Janssen Pharmaceutica (Beerse, Belgium) outside the

submitted work. Simon Lovestone reports other from Janssen-Cilag Ltd (High Wycombe, UK) and grants from AstraZeneca plc (Cambridge, UK) and European Federation of Pharmaceutical Industries and Associations (Brussels, Belgium) outside the submitted work. In addition, Simon Lovestone has patents issued and pending related to biomarkers for Alzheimer's disease. He also reports membership of the Efficacy and Mechanism Evaluation Strategy Group from 2015 to 2019 and of the Medical Advisory Board of SomaLogic (Boulder, CO, USA) up to 2019 and other consultancy for Merck Sharp & Dohme Corp., Eli Lilly and Company and Optum, Inc. (Eden Prairie, MN, USA). Clive Ballard reports grants and personal fees from Acadia Pharmaceutical Company (San Diego, CA, USA) and Lundbeck A/S (Copenhagen, Denmark) and personal fees from Roche Holding AG, Otsuka Pharmaceutical Co., Ltd (Tokyo, Japan), Novartis International AG (Basel Switzerland), Eli Lilly and Company and Pfizer Inc. (New York, NY, USA) outside the submitted work.

# Scientific summary

## Background

Alzheimer's disease is a major public health issue, with approximately 700,000 people in the UK suffering from dementia, some 400,000 of whom have Alzheimer's disease. The imperative to discover and develop treatments that can stop or at least delay disease progression is clear. None of the drug treatments licensed for Alzheimer's disease has been shown to affect progression of the illness and, despite a better understanding of the pathogenesis of Alzheimer's disease, clinical trials of potentially disease-modifying treatments so far undertaken have had disappointing results.

There is a substantial body of evidence to indicate that minocycline may be neuroprotective in neurodegenerative diseases such as Alzheimer's disease. Although the primary neuroprotective target of minocycline in the central nervous system is not known, the principal effects of minocycline include inhibition of microglial activation, attenuation of apoptosis and suppression of the production of reactive oxygen species. Minocycline is arguably the most promising off-patent candidate for Alzheimer's disease modification that is not currently in trials. Furthermore, minocycline is cheap and well tolerated.

## Objectives

The Minocycline in Alzheimer's Disease Efficacy (MADE) trial was a multicentre, randomised controlled trial in very mild Alzheimer's disease that primarily aimed to determine whether or not minocycline is superior to placebo in affecting the disease course, over a 2-year period, as measured by rate of decline in cognition (assessed via the standardised Mini Mental State Examination score) and function (assessed via the Bristol Activities of Daily Living Scale score). The study also compared the safety and tolerability of minocycline at doses of 200 and 400 mg per day.

## Methods

The MADE study was a Phase II, three-arm, randomised, double-blind, multicentre trial with a semifactorial design. Patients with very mild Alzheimer's disease (as assessed by having a standardised Mini Mental State Examination score of > 23 points and assessed by the National Institute on Aging–Alzheimer's Association's criteria) were identified from memory services, both within the 32 participating NHS trusts and within the network of memory services supported by the Dementias and Neurodegenerative Diseases Research Network.

Inclusion criteria were:

- a diagnosis of National Institute of Neurological and Communicative Disorders and Stroke–Alzheimer's Disease Related Disorders Association (NINCDS–ADRDA)-possible or -probable Alzheimer's disease
- a standardised Mini Mental State Examination score of > 23 points
- consent to participate or agreement to participate if capacity to give informed consent was lost
- renal and hepatic function within normal limits
- taking Alzheimer's disease medication (i.e. memantine or cholinesterase inhibitor) on a stable dose for at least 8 weeks.

Exclusion criteria were:

- a known allergy to tetracycline antibiotics
- a serious or unstable medical condition that would represent contraindication to taking trial medication.

Following informed consent and completion of baseline assessment, participants were randomly allocated 1 : 1 : 1 to one of three treatment arms: arm 1 – 400 mg per day of minocycline; arm 2 – 200 mg per day of minocycline; or arm 3 – placebo. Participants continued treatment for 24 months. Participants, investigators and outcome assessors were blind to treatment allocation.

Primary outcome measures were the decline in the standardised Mini Mental State Examination and the Bristol Activities of Daily Living Scale scores of combined minocycline trial arms versus placebo. Outcomes were analysed by intention-to-treat repeated measures regression.

The secondary research objectives were to:

- establish safety and tolerability of minocycline at doses of 200 and 400 mg per day in patients with mild Alzheimer's disease
- establish whether or not 400 mg per day of minocycline offers superior neuroprotection than 200 mg per day of minocycline
- estimate the magnitude of effect sizes on cognitive and functional decline associated with any statistically significant positive treatment effects that will inform the design and powering of a future Phase III trial of definitive clinical effectiveness within the NHS.

## Results

Between 23 May 2014 and 14 April 2016, 554 participants from 32 UK memory clinics were randomised. For the 544 eligible participants, the mean age was 74.3 years and the average standardised Mini Mental State Examination score was 26.4 points. Significantly fewer participants completed 400 mg of minocycline treatment (29%, 53/184) than 200 mg of minocycline treatment (62%, 112/181) or placebo (64%, 114/179) ( $p < 0.0001$ ), mainly because of gastrointestinal symptoms ( $p = 0.0008$ ), dermatological side effects ( $p = 0.02$ ) and dizziness ( $p = 0.01$ ). Assessment rates were also lower in the 400 mg of minocycline treatment arm for standardised Mini Mental State Examination scores at 24 months [68% (119/174 expected) for 400 mg of minocycline vs. 82% (144/176) for 200 mg of minocycline vs. 84% (140/167) for placebo]. Decline in the standardised Mini Mental State Examination scores over the 24-month study period in the combined minocycline trial arms were similar to those in the placebo arm (4.1- vs. 4.3-point reduction;  $p = 0.9$ ), as was the decline in the 400 and 200 mg of minocycline treatment arms (3.3 vs. 4.7 points;  $p = 0.08$ ). Likewise, worsening of Bristol Activities of Daily Living Scale scores over 24 months was similar in all treatment arms (5.7 for the 400 mg of minocycline treatment arm, 6.6 for the 200 mg of minocycline treatment arm and 6.2 for the placebo arm; a  $p$ -value of 0.57 for minocycline vs. placebo, and a  $p$ -value of 0.77 for 400 vs. 200 mg of minocycline). Results were similar in different patient subgroups and in sensitivity analyses adjusting for missing data.

## Conclusions

The MADE trial has shown that, in patients with mild Alzheimer's disease, 24 months of minocycline treatment at the doses tested does not delay the progress of cognitive or functional impairment, as measured by the well-validated and widely used standardised Mini Mental State Examination and Bristol Activities of Daily Living Scale clinical rating scales. The trial has also established that

minocycline at a dose of 400 mg is poorly tolerated in this population, with fewer than one-third of participants completing 24 months' treatment. By contrast, 200 mg per day of minocycline is well tolerated, with participants allocated this treatment being no more likely to withdraw from trial medication than those taking placebo.

## Future work

The MADE study provides a framework for a streamlined trial design that can be usefully applied to test other disease-modifying therapies.

## Trial registration

This trial is registered as ISRCTN16105064 and EudraCT 2013-000397-30.

## Funding

This project was funded by the Efficacy and Mechanism Evaluation programme, a Medical Research Council and National Institute for Health Research (NIHR) partnership, and will be published in full in *Efficacy and Mechanism Evaluation*; Vol. 7, No. 2. See the NIHR Journals Library website for further project information.

## Criteria for inclusion in the *Efficacy and Mechanism Evaluation* journal

Reports are published in *Efficacy and Mechanism Evaluation* (EME) if (1) they have resulted from work for the EME programme, and (2) they are of a sufficiently high scientific quality as assessed by the reviewers and editors.

## EME programme

The Efficacy and Mechanism Evaluation (EME) programme funds ambitious studies evaluating interventions that have the potential to make a step-change in the promotion of health, treatment of disease and improvement of rehabilitation or long-term care. Within these studies, EME supports research to improve the understanding of the mechanisms of both diseases and treatments.

The programme support translational research into a wide range of new or repurposed interventions. These may include diagnostic or prognostic tests and decision-making tools, therapeutics or psychological treatments, medical devices, and public health initiatives delivered in the NHS.

The EME programme supports clinical trials and studies with other robust designs, which test the efficacy of interventions, and which may use clinical or well-validated surrogate outcomes. It only supports studies in man and where there is adequate proof of concept. The programme encourages hypothesis-driven mechanistic studies, integrated within the efficacy study, that explore the mechanisms of action of the intervention or the disease, the cause of differing responses, or improve the understanding of adverse effects. It funds similar mechanistic studies linked to studies funded by any NIHR programme.

The EME programme is funded by the Medical Research Council (MRC) and the National Institute for Health Research (NIHR), with contributions from the Chief Scientist Office (CSO) in Scotland and National Institute for Social Care and Health Research (NISCHR) in Wales and the Health and Social Care Research and Development (HSC R&D), Public Health Agency in Northern Ireland.

## This report

The research reported in this issue of the journal was funded by the EME programme as project number 11/47/01. The contractual start date was in June 2013. The final report began editorial review in April 2019 and was accepted for publication in November 2019. The authors have been wholly responsible for all data collection, analysis and interpretation, and for writing up their work. The EME editors and production house have tried to ensure the accuracy of the authors' report and would like to thank the reviewers for their constructive comments on the final report document. However, they do not accept liability for damages or losses arising from material published in this report.

This report presents independent research. The views and opinions expressed by authors in this publication are those of the authors and do not necessarily reflect those of the NHS, the NIHR, the MRC, NETSCC, the EME programme or the Department of Health and Social Care. If there are verbatim quotations included in this publication the views and opinions expressed by the interviewees are those of the interviewees and do not necessarily reflect those of the authors, those of the NHS, the NIHR, NETSCC, the EME programme or the Department of Health and Social Care.
