## **Carbon Dioxide Insufflation and Brain Protection During Open Heart Surgery: A Randomised Controlled Trial**

### **The CO<sub>2</sub> Study**

|             |                |
|-------------|----------------|
| IRAS ID     | 278171         |
| ISRCTN No   | 30671536       |
| EUDRACT no. | 2020-001322-54 |

**This protocol has regard for the Health Research Authority guidance**

#### ***Details of Sponsor***

University Hospitals Bristol and Weston NHS Foundation Trust  
Research & Innovation Department  
Level 3, Education Centre  
Upper Maudlin Street  
Bristol BS2 8AE

Tel: 0117 342 0233  
Fax: 0117 342 0239

#### ***Chief Investigators & Research Team Contact Details***

##### *Chief Investigator*

Dr Ben Gibbison

University of Bristol

Tel: 07931568135

Email: [ben.gibbison@bristol.ac.uk](mailto:ben.gibbison@bristol.ac.uk)

*Senior Statistician and co-applicant*  
Professor Chris Rogers  
University of Bristol  
Tel: 0117 455 7909  
Email: [chris.rogers@bristol.ac.uk](mailto:chris.rogers@bristol.ac.uk)

*Associate Professor in Cardiac Surgery and applicant*  
Associate Professor Umberto Benedetto  
University of Bristol  
Tel: 0117 342 8854  
Email: [umberto.benedetto@bristol.ac.uk](mailto:umberto.benedetto@bristol.ac.uk)

*Senior Research Fellow and co-applicant*  
Dr Maria Pufulete  
Bristol Trials Centre  
University of Bristol  
Tel: 0117 342 4195  
Email: [maria.pufulete@bristol.ac.uk](mailto:maria.pufulete@bristol.ac.uk)

*Senior Research Fellow and co-applicant*  
Dr Lucy Culliford  
Bristol Trials Centre  
University of Bristol  
Tel: 0117 342 2526  
Email: [lucy.culliford@bristol.ac.uk](mailto:lucy.culliford@bristol.ac.uk)

*Professor of Cardiac Surgery and co-applicant*  
Professor Gianni Angelini  
University of Bristol  
Tel: 0117 342 3145  
Email: [g.d.angelini@bristol.ac.uk](mailto:g.d.angelini@bristol.ac.uk)

*Director of the Wellcome Centre for Integrative Neuroimaging and co-applicant*  
Heidi Johansen-Berg  
University of Oxford  
Tel: 01865 610469  
Email: [heidi.johansen-berg@ndcn.ox.ac.uk](mailto:heidi.johansen-berg@ndcn.ox.ac.uk)

*Research Fellow and co-applicant*  
Natalie Voets  
University of Oxford  
Tel: 01865 611462  
Email: [natalie.voets@ndcn.ox.ac.uk](mailto:natalie.voets@ndcn.ox.ac.uk)

*Neuroradiologist and co-applicant*  
Dr Pieter Pretorius  
Oxford University Hospitals NHS Foundation  
Tel: 01865 234272  
Email: [Pieter.Pretorius@ouh.nhs.uk](mailto:Pieter.Pretorius@ouh.nhs.uk)

*Cardiothoracic Surgeon and co-applicant*  
Mr Rana Sayeed  
Oxford University Hospitals NHS Foundation Trust  
Tel: 07894748621  
Email: [Rana.Sayeed@ouh.nhs.uk](mailto:Rana.Sayeed@ouh.nhs.uk)

*Consultant Cardiac Surgeon and co-applicant*  
Mr Enoch Akowuah  
South Tees Hospitals NHS Foundation Trust  
Tel: 07727997741  
Email: [enoch.akowuah@nhs.net](mailto:enoch.akowuah@nhs.net)

*Trial Manager*  
Ms Alison Bamford  
Bristol Trials Centre  
University of Bristol  
Tel: 0117 455 1782  
Email: [alison.bamford@bristol.ac.uk](mailto:alison.bamford@bristol.ac.uk)

*Consultant Cardiac Surgeon and co-applicant*  
Professor Massimo Caputo  
University of Bristol  
Tel: 0117 342 8857  
Email: [M.Caputo@bristol.ac.uk](mailto:M.Caputo@bristol.ac.uk)

## 1. Trial summary

Brain dysfunction and injury is a common complication after heart surgery. It affects about 6 in every 10 people who undergo open heart surgery. It can be severe and permanent, for example stroke, although this is rare. In most people degree of dysfunction and injury is milder, manifesting as problems with memory and thinking. In some patients, these problems can persist for up to one year after heart surgery and may increase the risk of developing dementia.

Surgeons believe that brain dysfunction partly results from microscopic air bubbles (microemboli) that enter the bloodstream when the heart is opened during surgery. These air bubbles are carried to the brain where they can get stuck in the small blood vessels and prevent blood from reaching that area of the brain, damaging, and eventually killing, surrounding nerve cells. One way that surgeons think they can reduce the number of air bubbles entering the bloodstream is by gently blowing the gas carbon dioxide into the area they are operating on. Carbon dioxide dissolves in blood much more easily than air, so it can displace air bubbles. However, there is little evidence that this technique, known as carbon dioxide insufflation (CDI), prevents brain injury after cardiac surgery.

The CO<sub>2</sub> study will test the hypothesis that CDI prevents brain injury in patients undergoing heart surgery. Patients who are undergoing surgery to repair or replace one or more of their heart valves will be randomised into two groups; one group will receive carbon dioxide gas blowing into the heart and the other group will receive medical air (placebo). Medical air has no effect on the amount of air entering the bloodstream. Neither surgeons nor participants will know which type of gas is being used; only the person operating the cylinder will know. Everything else about the operation will be exactly the same. Participants will have a very sensitive brain scan (diffusion weighted magnetic resonance imaging, or DW MRI) between 2 and 10 days after their surgery. This is safe and should take no more than 30 minutes. Participants will also complete tests and questionnaires to assess brain and physical function and their quality of life before and 3 months after the operation. We will also collect information about how the operation went and any complications that the patients experience during and after the surgery, for example, strokes and kidney damage.

We hope to recruit 530 patients from at least eight UK NHS cardiac surgery centres into the trial. The trial is expected to take about 3 and half years to complete. We also want to do a small sub-study within the trial to determine whether CDI does lead to fewer air bubbles entering the circulation and whether fewer air bubbles means less damage to the brain. We will ask patients taking part at the Bristol centre (expected to be around 100 participants) to have an ultrasound scan of the main artery going to their head during their operation. The ultrasound scan is safe and will not delay the operation. The scan will allow the number of air bubbles entering the blood stream to be counted using a computer. This information can be reviewed against the brain scan to see if patients with fewer bubbles have fewer areas of damage in their brains.

## 1.1 Trial schema

**Figure 1 Trial schema**

## **2. Background & Rationale**

### **2.1 Brain injury and dysfunction after cardiac surgery**

Brain injury and dysfunction is a common complication after cardiac surgery and significantly increases the likelihood of patients requiring long-term care. Peri-operative stroke occurs in 2-6% of all patients (1). More than 20% of patients over 65 years of age and 33% of patients over 80 years of age experience post-operative delirium (1, 2). Post-operative cognitive dysfunction is estimated to affect more than 80% of patients at discharge, and persist in 25% of all patients at 1 year (3). Brain injury may also trigger chronic or progressive dementia (4).

It is assumed that brain injury is triggered by the release of microemboli (microscopic atherosclerotic particles or air bubbles) in the blood stream, which are carried to the brain. Indeed, intraoperative transcranial doppler (TCD) ultrasound monitoring demonstrates showers of small particulate or air emboli during cardiac and vascular manipulations (5). However, the relationship between intraoperative brain embolic load and brain injury still needs to be clarified. Some studies have reported that the embolic burden detected by TCD monitoring is associated with early cognition deficits while others have not confirmed this finding (6, 7).

### **2.2 Magnetic resonance imaging (MRI) to detect perioperative brain injury**

MRI examination of the brain is the “gold standard” for identifying and quantifying peri-operative brain injury (8) and has been used widely in randomised controlled trials (RCTs) investigating neuroprotective interventions in cardiac surgery (9-11). A variety of imaging techniques are applied to identify markers of such injury, including diffusion weighted imaging (DWI). The main advantage of DWI is that lesions typically appear within 2 hours of surgery and disappear after two weeks, therefore, new acute lesions represent “new” injury, so a baseline scan is not required to confirm that the lesion was not present before surgery. Another advantage is that the new framework for defining stroke proposed by the American Heart Association/American Stroke Association (8) includes neuroimaging (together with clinical or pathological evidence), so lesions found on DWI count as “silent” brain injury even in the absence of obvious clinical findings.

DWI lesions following left heart valve surgery are reported in about 50% of patients (5, 9). These lesions are multiple and very small (1-10mm in diameter and 32-750mm<sup>3</sup> in volume). They are located in all cerebrovascular territories, but more frequently in frontal and watershed border zones and the pattern of distribution confirms an embolic basis. Few (~9%) are associated with overt clinical signs of stroke so they represent “silent” brain injury in most cases (5, 9).

In population-based studies, a strong association has been found between “silent” brain injury identified by MRI and prevalent cognitive dysfunction and dementia (12-14), therefore it is plausible that a similar relationship exists between the appearance of new lesions after cardiac surgery and neurocognitive decline. Some preliminary data has suggested that the appearance of new “silent” brain lesions after cardiac surgery is associated with early post-operative

neurocognitive deterioration (15) although further investigations with longer follow-up are needed.

The use of post-operative cognitive dysfunction as a marker of peri-operative brain injury is problematic because of potential difficulties in ascertainment (5). Multiple factors affect neurocognitive test performance during the first week after surgery; namely treatment of post-operative pain, sedation, and other clinical recovery issues. Many, if not most, patients have some degree of cognitive dysfunction in the immediate post-operative period. Such a nearly universal occurrence is clearly not an appropriate marker of brain injury. Only after this period has passed can an objective assessment of the patient's cognition be performed; although the duration of altered cognition after surgery has not been defined clearly (5).

### **2.3 Intraoperative carbon dioxide insufflation (CDI)**

Most research on cerebral embolisation during cardiac surgery has focused on the issue of atherosclerotic microemboli. Devices designed to remove atherosclerotic microemboli from the bloodstream have been tested but they were not shown to reduce the burden of brain injury. One possible explanation is that the embolic load to the brain is mainly constituted by air (>80%) (16). Air microemboli form when the heart chambers and great vessels are opened, which inevitably fills them with air. The air will stay until it is mobilised into the arterial bed during and after weaning from cardiopulmonary bypass (CPB). Air microemboli are believed to lead to brain injury by occluding small vessels or causing endothelial damage (arterioles with inner diameter of 30-60µm) with relative distal ischemia. Manual de-airing techniques are commonly used to remove air from the heart chambers but, unfortunately, they are unable to fully eliminate air microemboli (17, 18).

Carbon dioxide insufflation (CDI) in the pericardial cavity has been proposed to reduce the formation of air microemboli during cardiac surgery (19, 20). The rationale behind its use is that carbon dioxide gas is more dense and more soluble than air, and can therefore displace air from the heart chambers, leading to fewer air microemboli entering the blood stream (20). However, the evidence that CDI prevents brain injury after cardiac surgery is still scarce (19). There are only four small, low-quality RCTs investigating the neuroprotective effect of CDI. They are all open trials at high risk of bias, are all based on neuro-psychometric tests performed at different time points with no brain imaging assessment and resulted in conflicting conclusions (21).

Lack of definitive evidence has resulted in a wide variability in CDI adoption in the clinical practice. Our survey has shown that surgeons are currently in equipoise, with proponents arguing for continued use of CDI, and opponents arguing that in addition to the increased costs (~£50-100 per patient), CDI may cause significant harm. In fact, CDI induces systemic hypercapnic acidosis (excess carbon dioxide causing the pH of blood and tissues to decrease), cerebral vasodilation and a relative increase in cerebral blood flow, which would counterbalance any protective effects because a higher number of microemboli (particulate or gaseous) could access the cerebral circulation (22). However, one RCT compared CDI vs. medical air insufflation in one hundred and twenty-five patients during open heart surgery and showed no

significant difference in the rate of cardiac complications experienced between the two groups (23).

## **2.4 Review of existing evidence**

We have conducted and recently published a systematic review and meta-analysis of all available RCTs investigating the efficacy of CDI versus standard de-airing techniques (21). Outcomes investigated were post-operative stroke, neurocognitive dysfunction, and in-hospital mortality. Pooled estimates were obtained using random-effects models to account for clinical diversity and methodological variation between studies. Eight RCTs were identified comparing CDI vs. standard de-airing but only four studies reported on the incidence of post-operative neurocognitive decline (23-25); 283 randomised to CDI, 284 randomised to standard de-airing. Most studies were small (<100 patients) and at high risk of bias. Type and timing of neurocognitive function tests varied among studies. Different methods were used for delivery of carbon dioxide. In-hospital mortality was 2.1% vs 3.0% in the CDI and standard de-airing (control) groups, respectively (risk difference (RD) 0%; 95% CI -2% to 2%). Incidence of stroke was 1.0% vs 1.2% (RD 0%; 95% CI -1% to 2%) and neurocognitive dysfunction was 12% vs 21% (RD: -7%; 95% CI -0.22% to 8%) in the CDI and control group, respectively. The results of the meta-analysis were influenced by our decision to include a trial with no events (23), which resulted in a more conservative estimate of treatment effect. Excluding this trial from the analysis suggested a protective effect of CDI on neurocognitive function (OR 0.46, 95%CI 0.22 to 0.96).

## **3. Rationale**

Nearly 40,000 people in the UK (<http://bluebook.scts.org/>) and many more worldwide have cardiac surgery annually. Ischaemic brain injury represents a common complication and is associated with increased hospital stay, slow recovery, poor quality of life, further health care resource use and reduced long term survival. Cardiac surgery is increasingly being offered to older, higher-risk patients with comorbidities, so the incidence of neurological complications is likely to increase in the future. CDI is a widely used intervention, which many surgeons believe improves neurological outcomes. However, there is little evidence for its efficacy or risk of harm and its routine use is not recommended and surgeons are currently in equipoise regarding its adoption.

The CO2 study will assess the neuroprotective effect of CDI versus placebo (medical air insufflation) in addition to standard de-airing in patients undergoing left side heart valve surgery. In addition, the CO2 study will investigate the relationship between cerebral air embolic load and peri-operative brain injury detected by MRI and the relationship between perioperative brain injury and post-operative neurocognitive function.

## **4. Aims and objectives**

The CO2 study aims to evaluate the efficacy and safety of CDI in patients undergoing planned open left side heart valve surgery.

It is hypothesised that in patients undergoing open heart valve surgery via partial or full sternotomy or thoracotomy, CDI plus standard de-airing is protective against ischaemic brain injury caused by cerebral embolisation (air microemboli) compared with medical air insufflation (placebo) plus standard de-airing.

Specific objectives of the trial are to evaluate:

1. The difference between groups receiving CDI or medical air insufflation in the incidence of acute clinical or radiographic ischemic brain injury between 2 and 10 days post procedure (primary outcome)
2. The difference between groups receiving CDI or medical air insufflation with respect to a range of secondary outcomes (clinical, DWI lesion characteristics, adverse events, and patient-reported)
3. The association between the burden and location with new ischemic brain lesions detected with DWI and post-operative neurocognitive function assessed by standard neurocognitive function tests

A mechanistic sub-study will also be conducted. Specific objectives of the mechanistic sub-study are to determine whether there is a relationship between:

1. Intraoperative air embolic load (total number of gaseous emboli and total number of particulate emboli) detected by TCD
2. Middle cerebral artery (MCA) time averaged flow velocity detected by TCD
3. Tissue oxygen index (TOI) of the frontal lobes by Near Infrared Spectroscopy (NIRS)

and ischaemic brain injury detected by MRI, and whether these relationships differ between the CDI and medical air insufflation groups.

## **5. Primary and secondary outcomes**

### **5.1.1 Primary outcome**

The primary outcome is acute ischemic brain injury within 10 days post-surgery based on new brain lesions identified with DW MRI or clinical evidence of permanent brain injury according to the updated definition of stroke for the 21<sup>st</sup> century: symptoms persisting  $\geq 24$  hours in the brain, spinal cord or/and retina; not including cases of global ischemia (26).

All patients will be assessed by 1.5 or 3.0 T MRI between 2 and 10 days post-operatively. MRIs will be performed at each participating centre according to a standardised protocol and will be centrally analysed at the Wellcome Centre for Integrative Neuroimaging at the University of Oxford.

We will use the framework for assessing brain injury proposed by the American Heart Association/American Stroke Association for use in RCTs assessing neuroprotection during cardiovascular interventions (8). These guidelines recommend post-procedural brain DWI as the

gold standard in studies investigating devices or procedures designed to prevent iatrogenic or spontaneous acute neurological injury.

### **5.1.2 Secondary outcomes**

Data will be collected to characterise the following secondary outcomes:

1. Number and maximum diameter of DWI brain lesions
2. Objective quantification of the impairment caused by new ischemic brain injury assessed using the National Institutes of Health Stroke Scale (NIHSS)
3. Delirium assessed using the 3-minute diagnostic interview for Confusion Assessment Method (CAM)
4. Functional status assessed using the Barthel Index score
5. Neurocognitive function in 6 domains (verbal memory, visual memory, executive functioning, visuospatial or constructional praxis, attention, and information processing speed), assessed using the following tests:
  - a. Addenbrooke's Cognitive Examination III (ACE III)
  - b. Oral Trail making Tests A and B (oTMT A&B)
6. Quality of life assessed using the physical and mental subscales of the 12-Item Short-Form Health Survey (SF-12)
7. Composite of all-cause mortality, clinical stroke, or acute kidney injury within 30 days of surgery
8. Serious adverse events (SAEs) to 3 months
9. Survival to 3 months

All patients will be consented for passive follow up for up to five years after their surgery from NHS and national health and registration records to determine any association between silent brain lesions and long-term neurological outcomes (e.g. dementia).

### **5.1.3 Mechanistic sub-study outcomes**

1. Cerebral gaseous microembolic load assessed using TCD
2. Middle cerebral artery (MCA) time averaged flow velocity from both middle cerebral arteries
3. Tissue oxygen index (TOI) of the frontal lobes measured using NIRS

## **6. Plan of Investigation**

### **6.1 Trial design**

The CO2 study is a multicentre, parallel two-group placebo-controlled RCT in which participants, clinical care teams, members of the research team responsible for data collection and imaging assessors will be blinded to the treatment allocation (with the exception of the perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy, responsible delivering the study intervention).

### **6.2 Key design features to minimise bias**

Selection/allocation bias will be prevented by concealed randomisation. The allocation will not be revealed until sufficient information to uniquely identify the participant has been entered into the allocation database.

Performance bias will be minimised by blinding participants and the healthcare professionals looking after them to treatment allocation. We will also i) define the interventions and the standard protocols for all other aspects of care during the study, ii) define procedures for follow-up, iii) monitor adherence to the protocol. The patient information leaflet (PIL) and the process of obtaining informed consent will describe the uncertainty about the effects of CDI. Therefore, in the event of inadvertent unblinding of a participant, they should not have a strong expectation that any one method should lead to a more favourable result.

Detection bias will be minimised by blinding of outcome assessors and using outcome measures that are defined as far as possible on the basis of objective criteria. MRI will follow a standardised protocol and scans will be analysed centrally. Stroke will be defined using the American Heart Association / American Stroke Association updated definition of stroke (26). TCD ultrasound assessments will be standardised and conducted by personnel blinded to the allocation.

Attrition bias will be minimised by using established methods developed in the Bristol Trials Centre (BTC) to maximise the quality and completeness of the data (e.g. regular monitoring of data, detailed querying of data inbuilt into the study database, offering alternative methods for participating in follow-up (e.g. postal, online or telephone). Any instances of non-adherence will be fully documented and reviewed at study meetings and an action plan for maximising compliance drawn up as appropriate. Data will be analysed by intention to treat (i.e. according to the treatment allocation, irrespective of future management and events), and every effort will be made to include all randomised patients. Follow-up for the primary outcome should be complete for all patients.

Reporting bias will be minimised by pre-specifying study outcomes and following a detailed analysis plan which will be prepared in advance of any comparative analyses of the study data.

### **6.3 Setting**

Participants will be recruited from at least eight cardiac surgery centres in UK NHS hospitals.

### **6.4 Trial population**

Adults undergoing planned left side heart valve surgery.

#### **6.4.1 Inclusion criteria**

1. Age  $\geq$  50 years
2. Planned aortic or mitral valve surgical repair or replacement (with or without another procedure, e.g. coronary artery bypass graft) via a partial or full sternotomy or thoracotomy using central (i.e. aortic) or peripheral (i.e. femoral) perfusion cannulae

#### **6.4.2 Exclusion criteria**

1. Contraindication to medical carbon dioxide: acquired or genetic of acidosis (i.e. renal tubular acidosis)
2. Contraindication to MRI (e.g. known intolerance, permanent pacemaker in situ or expected implantation of a permanent pacemaker)
3. History of clinical stroke within 3 months prior to randomisation
4. Cardiac catheterisation within 3 days of the planned surgery
5. Cerebral and/or aortic arch arteriography or interventions within 3 days of the planned surgery
6. Active endocarditis at time of randomisation
7. Planned concomitant aortic procedure such as root replacement
8. Clinical signs of cardiogenic shock or treatment with IV inotropic therapy prior to randomisation
9. Previous cardiac surgery
10. Participation in an interventional (drug or device) trial
11. Unable to provide written informed consent
12. Prisoners

### **6.5 Randomisation**

Participants will be randomised as close to the planned operation as possible (ideally 30 minutes before the participant is taken to theatre), after consent has been given, baseline assessments have been completed and eligibility has been confirmed by the Principal Investigator, a delegated medically qualified doctor or Advanced Nurse Practitioner who has undergone suitable training.

Participants will be allocated in a 1:1 ratio to either CDI plus standard de-airing or medical air insufflation (placebo) plus standard de-airing. The allocation will be computer-generated and will be stratified by centre, type of procedure (i.e. valve only or valve combined with another procedure e.g. CABG) and whether planned surgical access is minimally invasive (e.g.

thoracotomy), by an independent BTC statistician, not involved in the study, before recruitment begins.

Randomisation will be performed using a secure internet-based randomisation system ensuring allocation concealment by a member of the research team not involved in data collection or participant follow-up.

## **6.6 Blinding**

Participants, their clinical care team (i.e. the surgeon, anaesthetist and those responsible for their post-operative care), research nurse(s) responsible for participant follow-up and imaging assessors will not be informed of the intervention allocation.

The perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy will be unblinded to the trial intervention allocated at randomisation in order to deliver the allocated intervention and monitor the participant throughout the surgery. Either the perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy or an unblinded member of the team will be responsible for carrying out the randomisation and preparing the unblinded case report form (CRF) with the treatment allocation. If an unblinded member of the team randomises the participant, they will hand documentation containing the treatment allocation and the relevant CRF in a sealed envelope to the perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy.

Following surgery the completed CRF will be entered into the database by either the perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy or the unblinded member of the team. This documentation will be stored separately to the rest of the CRFs to ensure blinding is maintained throughout the trial.

Any member of staff who accesses the sealed envelope containing the allocation details will have to record the reason for accessing the documentation on the relevant case report form.

Cylinders of carbon dioxide and medical air can be purchased in similar physical sizes, both are grey in colour and only the collars differ. The cylinder will be brought into theatre by the perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy. The cylinder and flowmeter will be covered with a sterile surgical drape/sleeve to maintain blinding. The insufflation flow rate will be standardised for both groups (5L/min).

There are no obvious clinical or other cues as to whether CDI or medical air was used, so we do not expect participants to be unblinded. Research Nurses responsible for data collection and participant follow-up will not randomise patients and will not be in the operating theatre. MRI scans will be analysed centrally. We will assess the success of blinding by asking the Research Nurse undertaking the assessments, after the three month follow up, and the Imaging Assessor,

following review of the DW-MRI brain, which treatment they think was received (Bang blinding index (27)).

## **6.7 Unblinding**

Requests to unblind on clinical grounds, e.g. to treat a complication, are not anticipated. However, if unblinding is requested during surgery on safety grounds, this will be facilitated by the perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy. Any such request will be fully documented including who requested the unblinding and the reason for unblinding.

Requests to unblind after leaving the operating theatre should not occur; given that the effect of CDI/medical air insufflation is strictly limited to the period of delivery in the operating room. Therefore, the management of any subsequent SAE would not be altered by knowledge of the allocation. Unblinding rates will be monitored throughout the trial by the study team and by the independent Data Monitoring and Safety Committee (DMSC) that will be established to oversee participant safety in the trial (see Section 11 for further details).

Participants will be made aware before entering the study that they will not be told which treatment they will receive until after the trial has completed.

## **6.8 Research procedures**

Participants will be required to do, or undergo, the following tasks or investigations specifically for the study which are also outlined in table 1.

### **Pre-surgery:**

- Read the CO2 study PIL (can be sent to the patient's home before the patient attends the hospital for their surgery)
- Provide informed consent to participate, if willing to do so
- Assessment of NIHSS, CAM, functional status (Barthel Index) and neurocognitive function (ACE III and oTMT A&B)  
Complete quality of life questionnaire (SF-12)

### **During surgery:**

- Receive the intervention allocated at randomisation during open heart valve surgery
- *If participating in the mechanistic sub-study (Bristol centre only), a transcranial doppler ultrasound of the middle cerebral artery and near infrared spectroscopy of the frontal lobe will be conducted during surgery*
- Assessment and reporting of any AEs and SAEs experienced

### **Post-surgery inpatient stay:**

- **Day 3** (between 3-5 days post-surgery): Assessment of NIHSS and CAM

- DW MRI brain scan ideally between 2 and 7, but no more than 10, days after surgery before hospital discharge
- Assessment and reporting of any AEs and SAEs experienced

#### **Post-discharge:**

- **Three months post-surgery conducted via videocall** Assessment of functional status (Barthel Index) and neurocognitive function (ACE III and oTMT A&B). Complete quality of life questionnaire (SF-12). Collection and assessment of any SAEs experienced after discharge from hospital. In exceptional circumstances this may be conducted via telephone or face to face.

#### **6.8.1 Neurocognitive function**

Neurocognitive function tests, assessing six domains; visual and verbal memory, executive functioning, visuospatial or constructional praxis, attention and information processing speed, will be performed by a member of the research team who has undergone suitable training.

The tests to assess neurocognitive function are:

- Addenbrooke's Cognitive Examination III (28)
- Oral trail making test part A and B (29, 30)

Tests will be performed prior to surgery and at three-month follow up and should take around 30 minutes to conduct.

#### **6.8.2 National Institutes of Health Stroke Scale**

National Institutes of Health Stroke Scale (NIHSS) will be used to assess any impairment that may have been caused by ischemic brain injury. The scale will be completed at the specified timepoints by a member of research team who has undergone suitable training. The scale should take around 15 minutes to conduct.

#### **6.8.3 Confusion Assessment Method**

Delirium will be assessed using the confusion assessment method algorithm three minute interview (31). The interview will be performed at the specified timepoints by a member of research team who has undergone suitable training. The interview should take around three minutes to conduct.

#### **6.8.4 Functional status**

Functional status will be assessed using the Barthel Index (32). The index will be performed at the specified timepoints by a member of the research team who has undergone suitable training. The score should take around 10 minutes to conduct.

### **6.8.5 Patient reported outcomes**

Quality of life (QoL) will be assessed using the physical and mental subscales of the 12-item Short-Form Health Survey (SF-12) (33). The patient should complete the questionnaire prior to surgery and at three-month follow up. Participants will be able to choose to receive the QoL questionnaire at three months by post (sent by BTC) or complete online via a secure website.

### **6.8.6 Diffusion Weighted Magnetic Resonance Imaging (DW MRI)**

All participants will undergo a 1.5 or 3.0 T diffusion weighted MRI (DW MRI) scan of their brain post-surgery. The DW MRI scan should be conducted in accordance with the CO2 MRI protocol. The scan will take approximately 30 minutes and will be completed as an inpatient as soon as possible after their surgery, ideally between 2-7 but no more than 10 days following surgery.

Scans will be transferred to the Wellcome Centre for Integrative Neuroimaging at the University of Oxford, who will perform a blinded review to assess any radiographic evidence of brain injury following surgery. Instructions on the transfer of images will be outlined in the imaging manual.

Participants will be asked to consent to the transfer of their DW MRI brain scans for review at entry to the trial.

### **6.8.7 Mechanistic sub-study – Bristol centre only**

Approximately one-hundred study participants from the Bristol centre will be asked to take part in the CO2 mechanistic sub-study. Consent to the sub-study is optional.

Sub-study participants will undergo a transcranial doppler (TCD) ultrasound of the middle cerebral artery during their surgery to monitor intraoperative air microemboli load and CBF. Participants will also undergo near-infrared spectroscopy (NIRS) to monitor the TOI of the frontal lobes during surgery.

The TCD and NIRS probes will be placed on the participant's head and secured before insufflation is initiated, until the procedure has been completed. Sub-study assessments will be performed by a Surgeon and Research Fellow who have undergone suitable training.

### **6.8.8 Non completion of research procedures**

Reasons for not completing any research procedure will be recorded and coded where possible. Missing items or errors on questionnaires will be dealt with according to the scoring manual or via imputation methods. Adherence rates will be reported in the results, including the numbers of patient who have withdrawn from the study, been lost to follow up or died. Causes of death will be recorded.

### **6.8.9 Abnormal findings**

Any abnormal findings identified because of the study assessments will be escalated to the relevant care teams for further investigation.

## **7. Trial intervention**

### **7.1 Trial interventions**

Study participants will be randomly allocated on a 1:1 ratio to receive insufflation with either:

- **IMP:** Medical carbon dioxide (carbon dioxide purity 99.5% v/v min)
- **Placebo:** Medical air (oxygen content 21%)

#### **7.1.1 Dosing schedule**

Insufflation, with either carbon dioxide or medical air, will be initiated at a flow rate of 5 litres per minute (5.0L/min) before cannulation for cardiopulmonary bypass (CPB) and continued until 10 minutes post-CPB.

The allocated gas will be insufflated into the cardiothoracic wound through a gas diffuser that provides an almost 100% carbon dioxide / medical air atmosphere in the wound, as per the centre's local procedure.

The diffuser will be placed in the surgical incision.

When applied, the cardiotomy suction will be limited to a maximum rate of 1.5 L/min and the rough suction will be set to 10 L/min to avoid affecting the carbon dioxide/air concentrations in the field.

#### **7.1.2 Surgical procedure**

Operations will be performed through a complete or limited median sternotomy or thoracotomy with CPB with either a roller or centrifugal pump and hollowfibre membrane oxygenator maintaining non-pulsatile perfusion at 2 to 3L/(min m<sup>2</sup>), an arterial line filter will be used, mean arterial pressure maintenance at 70 and 90 mm Hg, and patient temperature to be between 37°-32°C. Gas sweep flows will be adjusted to maintain PaCO<sub>2</sub> at 35-40 mmHg (4.6-5.2KPa) with the alpha stat method.

Standard cannulation will consist of arterial cannulation in the distal part of the ascending aorta and a 2-stage venous cannula inserted into the right atrium and the inferior venae cava. Mitral valve operations will be an exception, for this surgery bicaval cannulation will be used.

Peripheral cannulation will be carried out as per local procedure in minimally invasive procedures i.e. using the femoral artery.

Myocardial preservation with cardioplegia will be carried out as per local protocols.

#### **7.1.3 De-airing manoeuvres**

Surgeons should perform standard de-airing manoeuvres as per local procedures.

All other aspects of the participant's pre, intra and post-operative management will be in accordance with existing local protocols.

#### **7.1.4 Dose modifications**

Dose modifications are not expected to occur.

#### **7.1.5 Regulatory status**

Medical carbon dioxide and medical air are UK-licensed and commercially available on the UK market. For this trial it is acceptable to use any licenced supply of medical carbon dioxide or medical air.

In this trial, medical carbon dioxide and medical air will be used 'off label' as part of the open-heart valve repair or replacement surgery.

#### **7.1.6 Preparation and labelling**

It is recommended that cylinders of both trial interventions are ordered in the same size to prevent unblinding. If using BOC Ltd supplied gas, cylinder size E is recommended.

Two cylinders of the allocated trial intervention should be taken into the operating theatre to ensure sufficient supply is available for the procedure. Green tubing can be used to connect to both cylinders with a Y connector to ensure flow can be continuously delivered without unblinding, should both cylinders be required.

Surgical drapes should be placed over the cylinders before they are brought into the operating theatre to prevent unblinding.

All cylinders will be labelled, in the cylinder storage area, under the supervision of the site's trial pharmacist with annex 13 compliant labels and in accordance with Good Clinical Practice (GCP) and pharmacy department SOPs.

The contents of the label will be submitted and approved for use by the MHRA.

#### **7.1.7 Drug storage and supply**

Both carbon dioxide and medical air will be sourced locally by the research site pharmacy (or as per local pharmacy delegated arrangements) at market price. Supply levels should be monitored and re-ordered as applicable.

Carbon dioxide and medical air cylinders will be stored and handled as per the current SPC storage precautions, in accordance with GCP, Good Manufacturing Practice and pharmacy department SOPs.

### **7.1.8 Reference Safety Information**

Reference safety information, listed in the medical carbon dioxide SPC, section 4.8 undesirable events, are not applicable to the trial population given that these patients will be unconscious due to anaesthesia and on CPB at the time the trial intervention is received and therefore, cannot experience the listed side effects.

No expected events are listed in the medical air SPC section 4.8, 'undesirable events'. Section 4.8 of the medical carbon dioxide and medical air SPC will be regularly reviewed for updates to the undesirable events listed. If there are any updates these will be reviewed by the Chief Investigator and, in consultation with the Sponsor, a decision made whether the updated document will be submitted to the MHRA for use as the RSI in the trial.

### **7.1.9 Contraindications**

Participants who are known to have acquired or genetic acidosis (i.e. renal tubular acidosis) will be excluded from the trial.

### **7.1.10 Treatment adherence**

Withdrawals during treatment should not occur due to the nature and duration of the intervention; the duration of intervention is from before cannulation for CPB, until 10 minutes after CPB has stopped. Problems with adherence (e.g. failure to follow randomisation allocation) are also expected to be low. The perfusionist or member of the operating theatre staff who undertakes insufflation as part of their role and as per local policy will document whether the allocated treatment was given, if there were any deviations from the allocated intervention and the reason.

## **7.2 Duration of treatment period**

The duration of the treatment commences when the patient enters the operating room and concludes when the patient leaves the operating room after their surgery.

The duration of the procedure is expected to be between 2 hours and 4 hours.

**Table 1      Schedule of assessments**

|                                                                                                            | Baseline | Intraoperative | Post-surgery                              |                                                  |           |                                 |                              |

\* approximately 100 patients at the Bristol centre only

## **8. Data collection**

Each patient will be assigned a unique study number. All data recorded on paper relating to the participant will be located in CRF folders, which will be stored securely. Staff with authorisation to make changes to the study records, including the study database, will be listed on the study delegation log maintained at each centre.

Screening data will be collected for all patients undergoing open heart valve surgery considered for the study. Age, sex and Index of Multiple Deprivation (IMD) will be collected for all patients irrespective if they decline to participate. This information is collected to assess any difference in the patients that do not take part compared to patients that do, to establish if there are any socioeconomic barriers to participation.

Baseline data will be collected after consent. Consenting patients will be contacted by an authorised member of the local research team (as specified in the delegation log) who will provide the opportunity to understand the nature, significance, implications and risks of the trial so that they may make an informed decision if they should take part. If the patient decides to take part the member of the local research team will obtain informed consent.

Patients who choose to consent using electronic consent methods will verbally provide their email address to the local research team to receive a link to the electronic consent form.

Data collection will include the following elements:

- a) A screening log of all patients undergoing open heart valve surgery via partial or full sternotomy including age, sex and Index of Multiple Deprivation (IMD) for place of residence derived from the patient's residential postcode, as recorded in their hospital records.
- b) Patients approached and assessed against the eligibility criteria and, if ineligible, reasons for ineligibility.
- c) Consent information collected prior to randomisation for all participating patients.
- d) Baseline information (e.g. medical history and assessments) and neurocognitive function and quality of life (collected via questionnaire) collected for all participating patients.
- e) Data relating to surgery and hospital stay collected for all participating patients.
- f) Images from the post-operative DW MRI brain scan will be collected for all patients.
- g) Data on neurocognitive function and quality of life (collected via questionnaire), adverse events and resource use will be collected at three months post-surgery for all participating patients. Participants will be able to choose to receive the quality of life questionnaire by post or complete via an online secure website.

### **8.1 Definition of end of trial**

The definition of the end of the trial is the date when all patients have completed the three-month post-surgery follow-up, or are lost to follow-up, the database has been locked and all data queries have been resolved.

The end of the trial for an individual patient is defined as completion of the three-month post-surgery follow-up assessments.

Patients will be asked to consent to the collection of long term follow up data (via Government bodies NHS Digital, ISD Scotland or NHS Wales Informatics Service) for up to five years post-surgery for future ethically approved research.

## **9. Safety reporting**

### **9.1 Overview**

Serious and adverse events (AEs) will be recorded and reported in accordance with GCP guidelines and the BTC's Serious Adverse Events and Safety Reporting Standard Operating Procedure (see Figure 2).

### **9.2 Definitions**

Adverse event (AE) is any undesirable event in a subject receiving treatment according to the protocol, including occurrences which are not necessarily caused by or related to administration of the research procedures.

Adverse reaction (AR) is any undesirable experience that has happened to a subject while taking a drug that is suspected to be caused by the drug or drugs.

Serious adverse event (SAE) is any event which results in death, is life threatening, requires hospitalisation or prolongs hospitalisation, results in persistent or significant disability or incapacity.

Suspected serious adverse reaction (SSAR) is any serious adverse event that is suspected to be related to the drug or drugs being taken.

Suspected unexpected serious adverse reaction (SUSAR) is an untoward medical occurrence suspected to be related to the drug or drugs being taken that is not consistent with the applicable product information and is serious.

All AEs must be reviewed, and causality must be assessed by the Principal Investigator or delegated individual.

If an event meets any of the 'serious' criteria listed below it is classified as an SAE:

- a) Results in death
- b) Life threatening
- c) Requires hospitalisation (unless hospitalisation is pre-planned)
- d) Prolongation of existing hospitalisation
- e) Results in persistent or significant disability or incapacity
- f) Congenital anomaly / birth defect
- g) Any other event which may jeopardise the patient or require intervention to prevent one of the other outcomes listed above

**Figure 2. Serious adverse event reporting flow chart**

### 9.3 Period for recording adverse events

Data on adverse events will only be collected for the period of the participant's post-operative hospital stay.

### 9.4 Period for recording serious adverse events

Data will be collected on all SAEs that occur from randomisation until the three-month follow up visit using the relevant CRFs. The Principal Investigator or delegate will undertake causality assessment within 24hrs of the site becoming aware of the event to determine if onward reporting is required.

Between randomisation and discharge centres will expedite report all fatal and 'unexpected' non-fatal SAEs that occur to BTC within 24 hours of becoming aware, using an SAE report form.

Unexpected events are all events deemed related to the trial intervention or any event which is not listed as anticipated of surgery in the trial protocol.

The BTC will report all fatal and 'unexpected' non-fatal SAEs to the Sponsor.. The Sponsor will report SUSARs to the MHRA and copy all reports to the BTC. BTC will report SUSARS to the REC.

### 9.5 Expected adverse event association with trial intervention

There are no known expected adverse events from the trial intervention in this trial population. Any SAEs deemed related to the trial intervention are considered to be SUSARs and must be reported as per Figure 2.

### 9.6 Anticipated adverse events associated with surgery

In cardiac surgery, post-operative transient complications are expected and can be frequent. These are classified as 'anticipated adverse events of surgery'.

The AEs 'anticipated' in patients undergoing cardiac surgery are listed in Table 2.

**Table 2 Anticipated adverse events of surgery**

| Body system    | Anticipated adverse event                                                                                                                                                                                                         |

## **10. Trial methods**

To minimise bias, outcome measures are defined as far as possible on the basis of objective criteria. All personnel carrying out outcome assessments will be blinded; this will minimise detection and performance bias.

### **10.1 Source data**

Clinical outcome data will be collected using purpose-designed case report forms (CRFs), which will be completed at baseline, during the participant's surgery and post-operative inpatient stay until discharge, routine post-operative follow-up appointment and the three-month post-surgery follow up (see Table 1 for schedule of data collection). The primary data source for these data will be the participant's hospital notes.

### **10.2 Planned recruitment rate**

CDI can, in principle, be applied to most adults undergoing left side heart valve surgery. The 530 participants will be recruited from at least eight high-volume UK NHS cardiac centres. Potential participants will be identified prospectively from lists of patients having cardiac surgery. Research staff considered part of the clinical care team are permitted to access this information.

Based on an average of 250 procedures per year per centre (<http://bluebook.scts.org/>), we estimate that 70% of patients will be eligible and approached and that 30% of those approached will consent to take part which is in line with the average 35% consent rate achieved across five other adult cardiac surgery trials run in Bristol (n=3055 eligible patients, 1114 consented) that required similar participant involvement. This equates to projected recruitment rate of 35 patients/month when all centres are open to recruitment allowing for a staggered opening of the sites.

### **10.3 Participant recruitment**

Patients undergoing planned left side heart valve surgery will be invited to participate. All potential participants will be sent or given an invitation letter and PIL (approved by the local Research Ethics Committee (REC)) describing the study. Participant Identification Centres (PICs) may be used to identify and give the PIL to potentially eligible participants, aged 50 years and over and having their care transferred to a participating research site for elective open heart valve surgery.

The patient will have time to read the PIL and to discuss their participation with others outside the research team (e.g. relatives or friends) if they wish. Most patients will have at least 24 hours to consider whether to participate. In a few cases, this time interval may be as little as 12 hours, for example for patients admitted for urgent planned surgery without prior notification to the waiting list co-ordinator. Despite the short notice, it is important to include these patients for the applicability of the trial findings since about 40% of patients having cardiac surgery are admitted as urgent cases.

Potential participants will be identified and approached with information about the trial prior to their surgery. An initial eligibility check will be performed prior to giving any details about the trial to the patient.

Potential participants will be seen or contacted by a member of the local research team who will answer any questions and take informed consent if the patient decides to participate. Consent will be obtained either by face to face at a clinic appointment or remotely by telephone/video call or electronically using a purposed designed electronic database. The consent process will be described in detail in the study manual.

Details of all patients approached for the trial and reason(s) for non-participation (e.g. reason for ineligibility or patient decline) will be documented. Participant eligibility will be assessed in full as close to randomisation as possible.

#### **10.4 Discontinuation/withdrawal of participants**

Each participant has the right to withdraw at any time.

Withdrawals during treatment should not occur due to the nature and duration of the intervention; the duration of the intervention is from before cannulation for CPB and continued until 10 minutes post-CPB. However, a clinician may withdraw a participant at any time if they feel it is in the participant's best interests.

Participants withdrawn from their allocated intervention but willing to continue completing follow-up schedules will be encouraged to do so. If a participant withdraws, data collected up until that point will be included in the analyses.

Reasons for all discontinuations and withdrawals will be captured in the study database and reported.

#### **10.5 Frequency and duration of follow up**

After discharge from hospital, participants are followed up at three months after surgery. Data concerning health status will be collected by questionnaires.

#### **10.6 Likely rate of loss to follow-up**

Until discharge from hospital, the only losses to follow-up will be due to death or participant withdrawal; these losses are expected to be very few (<2%). We expect loss to follow-up at three months to be minimal (less than 5%); the Titre-2 trial (which randomised over 2000 cardiac surgery patients across 16 centres), achieved >95% follow-up to three months (34).

#### **10.7 Expenses**

Any documents that need to be returned by the participant will be given with a pre-paid envelope, so that no expenses are incurred.

If the post-operative DW MRI brain cannot be completed before discharge but the participant is willing to return within the 2-10 day timeframe to undergo the scan, then participants may claim for travel expenses. However, every attempt must be made to complete the DW MRI before the patient is discharged.

### **11.1 Sample size calculation**

#### ***11.1.1 Main trial***

The target sample size is 530 participants, 265 per group, which will provide 80% power at a 5% significance level (2-sided) to detect a 25% relative reduction in the incidence of post-operative cerebral infarcts with CDI, assuming a 48% rate in the placebo group. Missing data for the primary outcome is expected to be minimal as the DW MRI brain and assessment of stroke will be completed prior to the participant's discharge home. This sample size is a reduction from the original target of 704 participants, which provided 90% power to detect the same target difference under the same assumptions. The sample size has been reduced due to recruitment difficulties.

Data from our systematic review and meta-analysis (21) showed a 43% relative risk (from 21% to 12%) reduction in the incidence of neurocognitive decline with CDI. It also showed a 47% relative risk reduction in the incidence of stroke over time following the introduction of CDI in Bristol in 2006 from 3.4% in 2005 to 1.6% in 2008. This was estimated from research data on 1754 valve surgeries and 42 strokes. This provided the basis for the target effect size; it is less than the effect observed in our systematic review, which is likely to have overestimated the treatment effect based on small RCTs at unclear or high risk of bias.

The anticipated event rate in the placebo group was chosen based on a meta-analysis of all available observational studies where brain MRI was routinely performed early after open heart valve surgery. Eight studies were identified with sample sizes ranging from 15 to 129 participants and rates of new ischemic lesions at MRI ranging from 38% to 72%. The pooled random effects estimate of new ischemic lesions was 55% (95% CI 48% to 63%). Assuming a 48% event rate (the lower limit of the 95% CI) leads to a larger sample size (compared to assuming a 55% event rate).

#### ***11.1.2 Mechanistic sub-study***

There are no previous studies investigating the association between embolic load and brain injury post-cardiac surgery, but embolic load detected by TCD shows a strong correlation with DWI positive lesions ( $r=0.70$ ) during coil embolization of unruptured intracranial aneurysms (35). Assuming a weaker association during open heart surgery the sample size for sub-study has been set at approximately 100 participants (the estimated number of participants to be recruited in Bristol). A sample of 100 participants which will provide 90% power at a 5% significance level (2-sided) to detect a correlation of 0.32 (linear regression  $r$ -squared of 0.1).

### **11.2 Stopping rules (phase 1)**

There are three conditions that might lead the Trial Steering Committee (TSC) to recommend stopping the trial early:

1. A failure to recruit sufficient patients to meet the target sample size within the proposed duration of the grant and refusal of the funder to extend the duration of recruitment
2. A failure to deliver the intervention as allocated
3. A failure to complete the MRI scan according to the protocol before discharge after surgery

With respect to 1., NIHR-EME will formally review progress after six months of recruitment, with the option of a contract break to minimise financial risk to the NIHR if recruitment does not reach a predefined criterion. After six months of active recruitment 92 participants should have been recruited, if the target recruitment rate is being met. Accepting recruitment typically starts slowly and increases over time as the trial gets established and that there is some variability from one month to the next (e.g. recruitment is typically lower over Christmas and in the summer holiday period than at other times of year). Therefore, it is proposed that trial recruitment will be halted if;

- a) fewer than 69 have been recruited within six months and
- b) we are unable to provide a plan that satisfies the NIHR-EME to make up the shortfall of 23 participants (i.e. the target recruitment of 4-5 participants per centre per month is not being exceeded and all eligible surgeons are participating)

The BTC will prepare a report for the Trial Steering Committee (TSC) to consider and make a recommendation to the NIHR-EME.

With respect to 2. and 3., the BTC will monitor adherence to the protocol throughout the trial and will investigate all cases of non-adherence. The BTC will prepare a report for the TSC to consider and propose halting the trial if the reasons for non-adherence cannot be addressed satisfactorily.

In addition to monitoring recruitment and adherence, the Data Monitoring and Safety Committee (DMSC) will monitor safety outcomes and the assumptions underpinning the sample size calculation (i.e. the event rate in the placebo group). The DMSC may recommend stopping the trial if the accrued data suggest that the trial is unsafe for one or both groups of participants or that a study of 530 participants will be inadequate, and a larger trial is not feasible.

### **11.3 Plan of analysis – primary and secondary outcomes**

Analyses will be performed on the intention-to-treat basis and will be directed by a pre-specified statistical analysis plan. Analyses will use data from all patients randomised. Primary and secondary outcomes will be compared using generalised linear (binary and count variables), Cox proportional hazards (time to event variables), or linear mixed model (continuous variables) regression, with placebo as the reference group. Model validity will be checked using standard methods; if a model is a poor fit, alternative models or transformations will be explored. Outcomes analysed on a logarithmic scale were transformed back to the original scale after analysis and results presented as geometric mean ratios. Analyses will be adjusted for baseline

values, and stratification variables (centre fitted as a random effect where possible and type of surgery). Findings will be reported as effect sizes with 95% CIs.

#### **11.4 Plan of analysis - mechanistic studies**

The analyses of the association between new ischaemic brain injury detected by MRI and each of; intraoperative air embolic load, CBF and TOI will be exploratory. Correlations between measures will be investigated, both overall and by treatment group. Comparisons of measures between treatment groups will follow the analysis plan outlined above.

#### **11.5 Frequency of analyses**

The primary analysis will take place when follow-up is complete for all recruited patients. The value of including an interim will be discussed with the DMSC. Safety data will be reported to the DMSC approximately every six months, together with any additional analyses the committee request.

#### **11.6 Criteria for the termination of the trial**

The trial may be terminated early by the TSC. A decision to terminate may arise from a recommendation by the DMSC to stop the trial, for example based on *an interim analysis of the data from the trial* or if the results of another study make the completion of the trial unnecessary.

### **12. Trial management**

University Hospitals Bristol and Weston NHS Foundation Trust will act as Sponsor. Responsibility for running the CO2 study will be established via a collaboration agreement with the University of Bristol. Agreements between the Sponsor and participating centres will be required, as well as standard site initiation documents, before recruitment commences. The study will be conducted in accordance with GCP guidelines, the European Union Directive 2001/20/EC on clinical trials, the Data Protection Act and the UK Policy Framework for Health and Social Care Research. The trial will be registered on an open access clinical trial database (ISRCTN). Clinical trial documents will be archived and held by the Sponsor for 15 years after study closure in accordance with the standard operating procedures of the Sponsor and in compliance with the principles of GCP.

The study will be managed by the Chief Investigator (CI), with mentoring and support from senior members of the research team who will provide experience of implementing large scale clinical trials, and the Trial Manager, with full support from the wider BTC, which is a UK Clinical Research Collaboration registered clinical trial unit (UKCRC Reg. No 11). The BTC has an established track record of designing, conducting, managing and reporting multi-centre clinical trials. The BTC has experience in building study database systems and providing randomisation services.

The CI and BTC team will work with the co-applicants to prepare the final protocol and submit the REC, MHRA and associated HRA applications. The BTC will prepare the study manual, provide the randomisation service and design and implement the data management system.

The CI, BTC team and Sponsor will endeavour to ensure that the trial runs according to the agreed timetable, recruitment targets are met, the CRFs are completed accurately, the trial complies with relevant ethical and other regulatory standards, and that all aspects of the study are performed to the highest quality. The CI and BTC team will also train investigators at participating centres, check that centres are ready to start ("green light") and monitor their progress during the study. The Trial Manager will be the contact point to provide support and guidance to the participating centres throughout the study.

### **12.1 Day-to-day management**

The CO2 study will be managed by a Trial Management Group (TMG), which will meet face-to-face or by teleconference approximately monthly. The TMG will be chaired by the Chief Investigator and members of the named research team will be invited as appropriate (see Chief Investigator & Research Team Contact Details).

An appropriately qualified person by training will be responsible at each site for identifying potential trial participants, seeking informed participant consent, randomising participants, liaising with pharmacy, collecting trial data and ensuring the trial protocol is adhered to.

### **12.2 Monitoring of sites**

#### ***12.2.1 Initiation visit***

Before the study commences, training session(s) will be organised by the BTC. These sessions will ensure that personnel at each site involved fully understand the protocol, CRFs, the operational requirements of the study and the assessments to be conducted within the trial e.g. neurocognitive function tests.

#### ***12.2.2 Site monitoring***

The trial coordinating centre will carry out regular monitoring and audit of compliance of centres with GCP and data collection procedures described in section 7.3. Monitoring of data collection will be via the study database (checks for data completeness and routine data query review), which will be carried out on a regular basis. The Investigator Site File and CRFs will be monitored by site self-completed checklists at least once in the lifecycle of the trial. The TMG will review accumulating data on, including but not limited to, screening, eligibility, recruitment, data completeness, adherence to trial visits and procedures, adverse events and protocol deviations in the form of central monitoring reports generated approximately monthly.

### **12.3 Trial Steering Committee and Data Monitoring and Safety Committee**

An independent TSC will be established to oversee the conduct of the study. It is anticipated that the TSC will comprise the CI, an independent chair and at least two additional independent members, at least one of whom will be a patient/public representative. The TSC will develop terms of reference outlining their responsibilities and operational details. The TSC will meet before recruitment in the trial begins and then approximately every six months during the course of the study.

An independent DMSC will be established to review safety data during the course of the study and will advise on interim analyses. The DMSC will develop a charter outlining their responsibilities and operational details. The DMSC will meet jointly with the TSC, before recruitment in the trial begins and they will meet approximately every six months after recruitment has begun.

Stopping rules for the trial will be discussed at the first joint TSC/DMSC meeting, and decisions documented in the DMSC Charter.

## **13. Ethical considerations**

### **13.1 Review by an NHS Research Ethics Committee**

The research will be performed subject to a favourable opinion from an NHS REC and Health Research Authority (HRA) approval, including any provisions of a non-NHS site assessment form. Ethics review of the protocol for the trial and other trial related essential documents (e.g. PIL and consent form) will be carried out by a UK NHS REC. Any subsequent amendments to these documents will be submitted to the REC and HRA for approval prior to implementation.

### **13.2 Risks and anticipated benefits**

The conduct of this study will allow us to determine which of the treatments is the most clinically effective, as such, this study will allow us to make evidence-based recommendations for the treatment of this patient population.

There are no known risks or benefits in either intervention in this trial population; this will be quantified as part of this study.

### **13.3 Informing potential study participants of possible benefits and known risks**

Information about possible benefits and risks of participation will be described in the PIL.

### **13.4 Obtaining informed consent from participants**

All participants will be required to give written informed consent. This process, including the information about the trial given to patients in advance of recruitment, is described above in section 10.3.

The PI or members of the team delegated by the PI will be responsible for obtaining informed consent. The consent process will be described in detail in the study manual. Research personnel authorised to obtain consent will be recorded on the Delegation of Responsibilities Log. All individuals obtaining informed consent will have received GCP training.

### **13.5 Co-enrolment**

Subject to agreement with the Chief Investigator, a participant may be co-enrolled to a non-intervention study as well as to the CO2 study. A participant must not be co-enrolled to another intervention study while they are actively participating (up to the three-month follow up visit) in the CO2 study.

## **14. Research governance**

This study will be conducted in accordance with:

- The Medicine for Human Use (Clinical Trial) Regulations 2004
- Good Clinical Practice (GCP) guidelines
- UK Policy Framework for Health and Social Care Research

### **14.1 Sponsor approval**

Any amendments to the trial documents must be approved by the sponsor prior to submission to the HRA, REC and MHRA as applicable.

### **14.2 NHS confirmation of capacity and capability**

Confirmation of capacity and capability is required from each participating site prior to their participation in the trial.

Any amendments to the trial documents approved by the REC, HRA and MHRA (if applicable) will be submitted to participating sites for information and implementation, as required.

### **14.3 Investigators' responsibilities**

Investigators will be required to ensure that local research approvals have been obtained and that any contractual agreements required have been signed off by all parties before recruiting any participant. Investigators will be required to ensure compliance to the protocol and study manual and with completion of the CRFs. Investigators will be required to allow access to study documentation or source data on request for monitoring visits and audits performed by the Sponsor or the BTC or any regulatory authorities.

Investigators will be required to read, acknowledge and inform their trial team of any amendments to the trial documents approved by the REC that they receive and ensure that the changes are complied with.

#### **14.4 Monitoring by sponsor**

The study will be monitored and audited in accordance with University Hospitals Bristol and Weston's Monitoring and Oversight of Research Activity SOP, which is consistent with the UK Policy Framework for Health and Social Care Research and the Medicines for Human Use (Clinical Trials) Regulations 2004. All study related documents will be made available on request for monitoring and audit by the sponsor (or the BTC if they have been delegated to monitor see 7.2.2), the relevant REC and for inspection by the MHRA or other licensing bodies. A monitoring plan will be prepared by the Sponsor.

#### **14.5 Indemnity**

This is an NHS-sponsored research study. For NHS sponsored research if there is negligent harm during the clinical trial when the NHS body owes a duty of care to the person harmed, NHS Indemnity covers NHS staff, medical academic staff with honorary contracts, and those conducting the trial. NHS Indemnity does not offer no-fault compensation and is unable to agree in advance to pay compensation for non-negligent harm. Ex-gratia payments may be considered in the case of a claim.

#### **14.6 Clinical Trial Authorisation**

CDI is classed as an investigational medicinal product and a Clinical Trial Authorisation (CTA) from the MHRA must be in place before starting the trial.

### **15. Data protection and participant confidentiality**

#### **15.1 Data protection**

Data will be collected and retained in accordance with the UK Data Protection Act 2018 and UK General Data Protection Regulation (UK-GDPR) 2020.

#### **15.2 Data handling, storage and sharing**

##### **15.2.1 Data handling**

The CO2 study team will provide the Sponsor with a Data Management Plan prior to the study opening to recruitment.

Data will be entered into a purpose-designed server database hosted on the NHS network. Information capable of identifying participants and the nature of treatment received will be held in the database with passwords restricted to CO2 study staff at the participating site and the co-ordinating centre.

The database and randomisation system will be designed to protect patient information in line with data protection legislation. Trial staff will ensure that the participants' anonymity is maintained through protective and secure handling and storage of patient information at

participating sites and in accordance with ethics approval. All documents will be stored securely and only accessible by trial staff and authorised personnel. Data will be collected and retained in accordance with data protection legislation.

Access to the database will be via a secure password-protected web-interface. Study data transferred electronically to the University of Bristol network for statistical analyses will contain the participant's unique study identifier only and will not include any personal identifiable information. with the unique study identifier and transferred via a secure network. Participants will be identified by their initials and unique study identifier on the secure NHS hosted database. Data will be entered promptly, and data validation and cleaning will be carried out throughout the trial.

Each recruiting centre will have access to the study manual, which will cover database use, data validation and data cleaning. The BTC will maintain and update the study manual as required.

### **15.2.2 Data storage**

All study documentation will be retained in a secure location during the conduct of the study and for 15 years after the end of the study, when all patient identifiable paper records will be destroyed by confidential means. Where trial related information is documented in the medical records, these records will be identified by a label bearing the name and duration of the trial and clearly stating the 'do not destroy before' date. Where electronic records are in use, local site policy will be followed. In compliance with the MRC Policy on Data Sharing, relevant 'meta'-data about the trial and the full dataset, but without any participant identifiers other than the unique participant identifier, will be held indefinitely (University server).

### **15.2.3 Data sharing**

Data will not be made available for sharing until after publication of the main results of the study. Thereafter, anonymised individual patient data will be made available for secondary research, conditional on assurance from the secondary researcher that the proposed use of the data is compliant with the MRC Policy on Data Sharing regarding scientific quality, ethical requirements and value for money. A minimum requirement with respect to scientific quality will be a publicly available pre-specified protocol describing the purpose, methods and analysis of the secondary research, e.g. a protocol for a Cochrane systematic review. A second file containing patient identifiers would be retained for record linkage or a similar purpose, subject to confirmation that the secondary research protocol has been approved by a UK REC or other similar, approved ethics review body. Patient identifiers would not be passed on to any third party.

## **16. Dissemination of findings**

A full report of the trial findings will be provided to the EME. Findings of the trial will be presented at national and international conferences and published in peer-reviewed journals. We will link with the British Heart Foundation, with the valve group of the British Society of Cardiothoracic Surgeons (SCTS) to highlight the importance of effective neuroprotection during

open heart surgery. In view of the current variation in clinical practice, we will also link to guidelines committees of the European Society of Cardiothoracic Surgeons, of which the CI is a member, to produce a consensus paper and recommendations on the use of carbon dioxide insufflation for neuroprotection. Social networking media will be used to disseminate and publicise the trial via our website, Facebook and Twitter streams. PPI groups will be consulted to identify how we can best publicise the trial findings.

Expected outputs include publication of the trial results, informing clinicians and patients on the efficacy of carbon dioxide insufflation for preventing neurocognitive dysfunction after heart surgery. The results of the trial will inform national and international guidelines on optimising the care pathway for patients undergoing valve surgery.
